Category

1.1 Small Category

Before we define a category in full generality, we shall focus our attention on the notion of *small category*. This notion is interesting to us because while it essentially describes the notion of *category* itself, it remains simple enough to be compared with various other algebraic structures. For example, consider the case of a monoid: a monoid is essentially a set M together with a binary relation \circ defined on M which is associative, and an element e of M which acts as an identity element for \circ . In short a monoid is a tuple (M, \circ, e) containing some data, and which satisfy certain properties. The same is true of a *small category*: it is also a tuple containing some data, and which satisfy certain properties:

Definition 1 We call small category any tuple (Ob, Arr, dom, cod, id, \circ) with:

- (1) Ob $is \ a \ set$
- (2) Arr is a set
- (3) $\operatorname{dom}: \operatorname{Arr} \to \operatorname{Ob} \ is \ a \ function$
- (4) $cod : Arr \rightarrow Ob \text{ is a function}$
- (5) $id : Ob \rightarrow Arr is a function$
- (6) $\circ : Arr \times Arr \rightarrow Arr \text{ is a partial function}$
- (7) $g \circ f \text{ is defined } \Leftrightarrow \operatorname{cod}(f) = \operatorname{dom}(g)$
- (8) $\operatorname{cod}(f) = \operatorname{dom}(g) \Rightarrow \operatorname{dom}(g \circ f) = \operatorname{dom}(f)$
- (9) $\operatorname{cod}(f) = \operatorname{dom}(g) \implies \operatorname{cod}(g \circ f) = \operatorname{cod}(g)$
- (10) $\operatorname{cod}(f) = \operatorname{dom}(g) \wedge \operatorname{cod}(g) = \operatorname{dom}(h) \Rightarrow (h \circ g) \circ f = h \circ (g \circ f)$
- (11) $\operatorname{dom}\left(\operatorname{id}(a)\right) = a = \operatorname{cod}\left(\operatorname{id}(a)\right)$
- (12) $\operatorname{dom}(f) = a \implies f \circ \operatorname{id}(a) = f$
- (13) $\operatorname{cod}(f) = a \Rightarrow \operatorname{id}(a) \circ f = f$

where (7) – (13) hold for all $f, g, h \in Arr$ and $a \in Ob$:

So if $\mathcal{C} = (\mathrm{Ob}, \mathrm{Arr}, \mathrm{dom}, \mathrm{cod}, \mathrm{id}, \circ)$ is a small category, we have two sets Ob and Arr together with some structure defined on these sets. This feels very much like a monoid, except that we have two sets instead of one and it all looks more complicated. The set Ob is called the *set of objects* of the small category \mathcal{C} and is denoted Ob \mathcal{C} , while the set Arr is called the *set of arrows* of the small category \mathcal{C} and is denoted Arr \mathcal{C} . An element $x \in \mathrm{Ob} \ \mathcal{C}$ is called an *object* of \mathcal{C} , while an element $f \in \mathrm{Arr} \ \mathcal{C}$ is called an *arrow* of \mathcal{C} .

As part of the structure defined on the small category \mathcal{C} , we have two functions dom: Arr \to Ob and cod: Arr \to Ob. Hence, given an arrow f of the small category \mathcal{C} , we have two objects $\mathrm{dom}(f)$ and $\mathrm{cod}(f)$ of the small category \mathcal{C} . The object $\mathrm{dom}(f)$ is called the domain of f. The object $\mathrm{cod}(f)$ is called the codomain of f. Note that an arrow f of the small category \mathcal{C} is simply an element of the set Arr \mathcal{C} . So it is itself a set but it may not be a function. The words domain and codomain are therefore overloaded as we are using them in relation to a set f which is possibly not a function. Whenever f is an arrow of the small category \mathcal{C} and f are objets, it is common to use the notation f: f are f as a notational shortcut for the equations f and f and f are objects, it is important to guard against the possible confusion induced by the notation f are f b which does not mean that f is function. It simply means that f is an arrow with domain f and codomain f in the small category f.

One of the main ingredients of the structure defining a small category $\mathcal C$ is the partial function $\circ: \operatorname{Arr} \times \operatorname{Arr} \to \operatorname{Arr}$, called the *composition operator* in the small category \mathcal{C} . The domain of this partial function is made of all ordered pairs (g, f) of arrows in \mathcal{C} for which $\operatorname{cod}(f) = \operatorname{dom}(g)$. As already indicated in definition (1), we use the infix notation $g \circ f$ rather than $\circ (g, f)$ and the arrow $g \circ f$ is called the *composition* of g and f. Once again, we should remember that the notation $g \circ f$ does not mean that g or f are functions. They are simply arrows in the small category \mathcal{C} . One key property of the composition operator \circ is the associativity postulated by (10) of definition (1). Note that if $f: a \to b$ and $g: b \to c$, then from properties (8) and (9) of definition (1) we obtain $q \circ f: a \to c$. Furthermore, if $h: c \to d$ we have $h \circ q: b \to d$ and the arrows $(h \circ q) \circ f$ and $h \circ (q \circ f)$ are therefore well-defined arrows with domain a and codomain d. This shows that the expression involved in the associativity condition (10) of definition (1) is always meaningful, involving terms which are well-defined provided $g \circ f$ and $h \circ g$ are themselves well-defined, i.e. provided cod(f) = dom(g) and cod(g) = dom(h).

Finally, as part of the structure defining the small category C, we have a function $id : \mathrm{Ob} \to \mathrm{Arr}$ called the *identity operator* on the small category C. Hence, for every object a of C we have an arrow id(a) called the *identity at a*. Looking at property (11) of definition (1) we see that $id(a) : a \to a$. In other words, the arrow id(a) has domain a and codomain a. Furthermore, looking at properties (12) and (13) of definition (1), for every arrow $f : a \to b$, the composition arrows $id(b) \circ f$ and $f \circ id(a)$ are well-defined and both equal to f.

1.2 Category

The notion of *small category* defined in definition (1) is similar to that of any other algebraic structure the reader may be familiar with. It can safely be encoded in set theory as a tuple (which is a set) containing data (which are other sets) which satisfies certain properties. In set theory, everything is a set. A small category \mathcal{C} is a set, its collection of objects Ob \mathcal{C} is a set, its arrows Arr \mathcal{C} form a set, the functions dom, cod, id and the composition operator \circ are all sets (functions are typically encoded as sets of ordered pairs).

Category theory falls outside of set theory. While the definition of a category we provide below is formally identical to that of a small category, the object we are defining can no longer be encoded in general as an object of set theory. For example, say we want to speak about the universe of all sets or the universe of all monoids. These universes which are known as classes cannot be represented as sets. They are not objects of set theory. Or say we are working within the formal framework of a proof assistant such as Coq, Agda or Lean. These tools are based on type theory and do not fall within the scope of set theory. When defining a category, we assume some form of meta-theoretic context, some form of logic, some way of reasoning about objects which may not be sets, where some meaning is attached to the words tuple, collection, equality and map. This may sound all very fuzzy, yet we cannot be more formal at this stage.

Definition 2 We call category any tuple (Ob, Arr, dom, cod, id, \circ) such that:

- (1) Ob is a collection with equality
 (2) Arr is a collection with equality
- (3) $\operatorname{dom}:\operatorname{Arr}\to\operatorname{Ob}\ is\ a\ map$
- (4) $\operatorname{cod}:\operatorname{Arr}\to\operatorname{Ob}\ is\ a\ map$
- (5) $\operatorname{id}:\operatorname{Ob}\to\operatorname{Arr}\ is\ a\ map$
- (6) $\circ : Arr \times Arr \rightarrow Arr \text{ is a partial map}$
- (7) $g \circ f \text{ is defined } \Leftrightarrow \operatorname{cod}(f) = \operatorname{dom}(g)$
- (8) $\operatorname{cod}(f) = \operatorname{dom}(g) \Rightarrow \operatorname{dom}(g \circ f) = \operatorname{dom}(f)$
- (9) $\operatorname{cod}(f) = \operatorname{dom}(g) \implies \operatorname{cod}(g \circ f) = \operatorname{cod}(g)$
- $(10) \qquad \operatorname{cod}(f) = \operatorname{dom}(g) \, \wedge \, \operatorname{cod}(g) = \operatorname{dom}(h) \ \Rightarrow \ (h \circ g) \circ f = h \circ (g \circ f)$
- (11) $\operatorname{dom}\left(\operatorname{id}(a)\right) = a = \operatorname{cod}\left(\operatorname{id}(a)\right)$
- (12) $\operatorname{dom}(f) = a \implies f \circ \operatorname{id}(a) = f$
- (13) $\operatorname{cod}(f) = a \Rightarrow \operatorname{id}(a) \circ f = f$

where (7) - (13) hold for all $f, g, h \in Arr$ and $a \in Ob$:

So let $\mathcal{C} = (Ob, Arr, dom, cod, id, \circ)$ be a category: then \mathcal{C} is a tuple but it is no longer a tuple in a set-theoretic sense. We assume given some logical framework where the notion of tuple is clear, even if not formally defined. Furthermore, We are no longer imposing that Ob should be a set, but are instead using the phrase collection with equality, whatever this may mean in our given logical context. So we shall still make use of the notation Ob $\mathcal C$ but this will now refer to the collection of all objects of the category C. In fact, if a is an object of the category \mathcal{C} , we shall abuse notations somewhat by writing ' $a \in \text{Ob } \mathcal{C}$ ' or even simply $a \in \mathcal{C}$ to express the fact that a is an object of \mathcal{C} , being understood that this use of the set membership symbol '\in ' does not mean anything is a set. Since we are stepping out of set theory, the objects of the category \mathcal{C} may not be sets themselves. They are simply members of the collection Ob \mathcal{C} . However, properties (7) - (13) of definition (2) are all referring to equalities between objects such that cod(f) = dom(g). So it must be the case that the notion of equality be meaningful on the collection Ob \mathcal{C} . This explains our use of the phrase collection with equality: given $a, b \in \mathcal{C}$, the statement a = b while not a set-theoretic equality is nonetheless assumed to be defined.

Similarly, the *collection* of arrows of the category \mathcal{C} shall still be denoted Arr \mathcal{C} , but is no longer required to be a set. If f is an arrow of the category \mathcal{C} then f itself may not be a set and we may still write ' $f \in \text{Arr } \mathcal{C}$ ' simply to indicate that f is a member of the collection Arr \mathcal{C} . Properties (10), (12) and (13) of definition (2) are all referring to equalities between arrows so the collection Arr \mathcal{C} must have some notion of equality defined on it.

Since Ob and Arr are no longer sets in general, the maps dom: Arr \rightarrow Ob, cod: Arr \rightarrow Ob, id: Ob \rightarrow Arr and the partial map \circ : Arr \times Arr \rightarrow Arr cannot possibly be functions in the set-theoretic sense. So there must be some meaning to the word map (from one collection to another) in whatever logical framework we are working in. The collection Arr \times Arr is not a set, and is simply the collection of all 2-dimensional tuples made from Arr. Our using the word map rather than function in definition (2) is simply an attempt at reminding ourselves of the fact these are not set-theoretic functions, eventhough the words map and function are perfectly interchangeable in standard (set-theoretic) mathematics.

Functor

Natural Transformation

Adjunction

4.1 Definition

Definition 3 We call adjunction an ordered pair (F,G) where F is a functor $F: \mathcal{C} \to \mathcal{D}$ and G is a functor $G: \mathcal{D} \to \mathcal{C}$ while \mathcal{C} and \mathcal{D} are two locally-small categories for which there exists a natural isomorphism:

$$\alpha : \mathcal{D} \circ (F \times I_{\mathcal{D}}) \Rightarrow \mathcal{C} \circ (I_{\mathcal{C}^{op}} \times G)$$

in the functor category $[\mathcal{C}^{op} \times \mathcal{D}, \mathcal{S}et]$, where F also denotes $F : \mathcal{C}^{op} \to \mathcal{D}^{op}$.
